

The number of distinct care home patients co-prescribed specific combinations of dementia and antipsychotic drugs within the same month in 2025/26

Donepezil + Haloperidol: increased risk of confusion and cognitive decline.

Donepezil + Levomepromazine: effects on cognition and strong sedation may increase falls risk and delirium.

Memantine + Haloperidol: sedation, stiffness, or worsening cognitive function side effects in vulnerable patients.

Memantine + Levomepromazine: can increase sedation and anticholinergic burden, raising risks of confusion and reduced alertness.

Rivastigmine + Levomepromazine: levomepromazine can counteract cognitive benefits and increase sedation-related harms.

Edges represent co-prescribing frequency between dementia drugs and antipsychotics. Highlighted edges indicate clinically concerning or high-risk combinations. Node colour and shape distinguish drug classes. Edge width reflects prescribing frequency. Vertex size reflects the 'strength' of a vertex, or the total sum of its weight with other nodes. The same patient could appear in multiple edge, if they were prescribed three or given drugs with the same month. Care home patients must be co-prescribed drugs within the same month to be included within an edge weight.
